

Local Branching Process

We should never work directly on master branch. Master is the most stable branch. Create local branch by cutting the master branch and you can have local branches either by feature or bug or module etc.

Flow diagram-

Best practice is cut from master branch -> work on local branch then add and commit the code and raise PR.

Naveen team leader will first set up the project structure and push the skeleton code to remote.

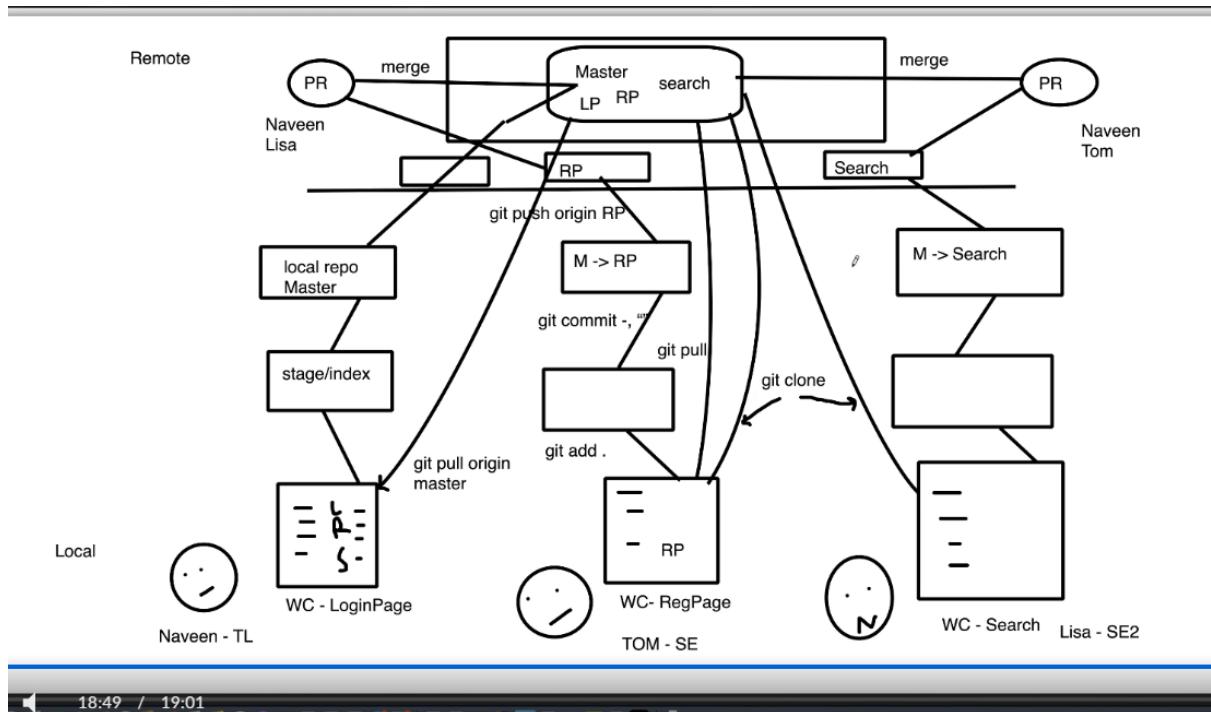

Naveen will work on master only because not much code is written.

If needed, then Naveen can create local branch also and prepare skeleton and then raise pr and merge with master also.

Raise a PR – here “pr” means pull request. Other developer or TL will check the code. After all ok then only merge the code.

Clone is one time activity or first-time activity.

Git pull is to take the latest code from master.
